Warranty
The material contained in this document is provided “as is,” and is subject to being changed, without notice, in future editions. Further, to the maximum extent permitted by applicable law, Agilent disclaims all warranties, either express or implied, with regard to this manual and any information contained herein, including but not limited to the implied warranties of merchantability and fitness for a particular purpose. Agilent shall not be liable for errors or for incidental or consequential damages in connection with the furnishing, use, or performance of this document or of any information contained herein. Should Agilent and the user have a separate written agreement with warranty terms covering the material in this document that conflict with these terms, the warranty terms in the separate agreement shall control.

Technology Licenses
The hardware and/or software described in this document are furnished under a license and may be used or copied only in accordance with the terms of such license.

Restricted Rights Legend
If software is for use in the performance of a U.S. Government prime contract or subcontract, Software is delivered and licensed as “Commercial computer software” as defined in FAR 252.227-7014 (June 1995), or as a “commercial item” as defined in FAR 2.101(a) or as “Restricted computer software” as defined in FAR 52.227-19 (June 1987) or any equivalent agency regulation or contract clause. Use, duplication or disclosure of Software is subject to Agilent Technologies’ standard commercial license terms, and non-DOD Departments and Agencies of the U.S. Government will receive no greater than Restricted Rights as defined in FAR 52.227-19(c)(1-2) (June 1987). U.S. Government users will receive no greater than Limited Rights as defined in FAR 52.227-14 (June 1987) or DFAR 252.227-7015 (b)(2) (November 1995), as applicable in any technical data.

Safety Notices

CAUTION
A CAUTION notice denotes a hazard. It calls attention to an operating procedure, practice, or the like that, if not correctly performed or adhered to, could result in damage to the product or loss of important data. Do not proceed beyond a CAUTION notice until the indicated conditions are fully understood and met.

WARNING
A WARNING notice denotes a hazard. It calls attention to an operating procedure, practice, or the like that, if not correctly performed or adhered to, could result in personal injury or death. Do not proceed beyond a WARNING notice until the indicated conditions are fully understood and met.

Introduction to the Preparative Pump

The preparative pump is a cam driven pump, with fixed stroke and two parallel pistons, each with (identical ball and seat) inlet and outlet valve. Each of the two pump pistons is capable of delivering a maximum of 50 ml/min flow at up to 400 bar pressure.

The two cams have overlapping delivery cycles. Compression losses are calculated and smooth delivery is ensured through variation of the motor speed over the pump cycle.

The pistons are guided through two seals each. The gap between those seals is connected to capillary fittings, this way seal wash is not only an option, but integral part of every pump. A peristaltic pump, to automate seal wash, is also part of the system.

---

**Figure 1** Overview of the Preparative Pump
Hydraulic Path Overview

The pump flow leaving the pump head passes through the multi-assembly, which combines the flow of the two pistons, filters the solvent and contains a pressure sensor to monitor system pressure. No hydraulic damper is included in the system. This makes very fast gradients possible. From the multi-assembly the flow is routed to the purge valve and from there either directly into waste or on to the next module (normally injection valve or sampling device).

Gradients are formed with two combined pumps, as high pressure gradients. The combined flow, is flowing through a passive mixer, to smooth composition. With its high pressure mixing principle gradient systems and the usually high flow rates, no degassing of solvents is necessary.

To avoid outgassing in the detector cell a back pressure regulating device is recommended for applications that demand it.

Figure 2  Schematics of the Preparative Pump
How Does Compressibility Compensation Work?

The compressibility of the solvents in use will affect retention-time stability when the back pressure in the system changes (for example, ageing of column). In order to minimize this effect, the pump provides a compressibility compensation feature which optimizes the flow stability according to the solvent type. The compressibility compensation is set to a default value and can be changed through the user interface.

Without a compressibility compensation the following will happen during a stroke of the first piston. The pressure in the piston chamber increases and the volume in the chamber will be compressed depending on backpressure and solvent type. The volume displaced into the system will be reduced by the compressed volume.

When a compressibility compensation value for the pump head is set, the pump processor calculates a compensation volume that depends on the system pressure and the selected compressibility value. The pump has a fixed stroke. To compensate for compressibility losses, the speed of the piston movement has to be varied during the different parts of each stroke.
Early Maintenance Feedback (EMF)

The early maintenance feedback (EMF) feature monitors the usage of specific components in the instrument, and provides feedback when the user-settable limits have been exceeded. The visual feedback in the user interface provides an indication that maintenance procedures should be scheduled.

For details on EMF counters and how to use them, see Agilent Lab Advisor.
Instrument Layout

The industrial design of the module incorporates several innovative features. It uses Agilent’s E-PAC concept for the packaging of electronics and mechanical assemblies. This concept is based upon the use of expanded polypropylene (EPP) layers foam plastic spacers in which the mechanical and electronic boards components of the module are placed. This pack is then housed in a metal inner cabinet which is enclosed by a plastic external cabinet. The advantages of this packaging technology are:

• virtual elimination of fixing screws, bolts or ties, reducing the number of components and increasing the speed of assembly/disassembly,

• the plastic layers have air channels molded into them so that cooling air can be guided exactly to the required locations,

• the plastic layers help cushion the electronic and mechanical parts from physical shock, and

• the metal inner cabinet shields the internal electronics from electromagnetic interference and also helps to reduce or eliminate radio frequency emissions from the instrument itself.
The Electronics

The electronics are comprised of four main components:

- The preparative pump main board (PPM), see “Preparative Pump Main Board (PPM)” on page 150.
- Power supply, see “Main Power Supply Assembly” on page 164.

Optional:

- Interface board (BCD/external contacts), see “BCD / External Contact Board” on page 155
- LAN Communication Card, see “LAN Communication Interface Board” on page 157.

Main Board

The board controls all information and activities of all assemblies within the module. The operator enters parameters, changes modes and controls the module through interfaces (CAN, GPIB or RS-232C), connected to the user-interfaces.

Main Power Supply Assembly

The main power supply comprises a closed assembly (no on-site repair possibility). The power supply provides all DC voltages used in the module except for the voltages supplied by the lamp power supply to the deuterium and tungsten lamps in the detectors.

The line voltage can vary in a range from 100 – 240 volts AC ± 10% and needs no manual setting.

Optional Interface Boards

The Agilent 1200 Series modules have one optional board slot that allows to add an interface board to the modules. Optional interface boards for the Agilent 1200 Series are:

- BCD Board
- LAN Communication Card
Electrical Connections

- The GPIB connector is used to connect the module with a computer. The address and control switch module next to the GPIB connector determines the GPIB address of your module. The switches are preset to a default address and is recognized once after power is switched ON.

- The CAN bus is a serial bus with high speed data transfer. The two connectors for the CAN bus are used for internal Agilent 1200 Series module data transfer and synchronization.

- One analog output provides signals for integrators or data handling systems.

- The interface board slot is used for external contacts and BCD bottle number output or LAN connections.

- The REMOTE connector may be used in combination with other analytical instruments from Agilent Technologies if you want to use features such as start, stop, common shut down, prepare, and so on.

- With the appropriate software, the RS-232C connector may be used to control the module from a computer through a RS-232C connection. This connector is activated and can be configured with the configuration switch. See your software documentation for further information.

- The power input socket accepts a line voltage of 100 – 240 volts AC ± 10% with a line frequency of 50 or 60 Hz. Maximum power consumption is 220 VA. There is no voltage selector on your module because the power supply has wide-ranging capability. There are no externally accessible fuses, because automatic electronic fuses are implemented in the power supply. The security lever at the power input socket prevents the module cover from being taken off when line power is still connected.

NOTE
Never use cables other than the ones supplied by Agilent Technologies to ensure proper functionality and compliance with safety or EMC regulations.

- CAN connectors as interface to other Agilent 1200 Series modules,
- GPIB connector as interface to the Agilent ChemStation,
- RS-232C as interface to a computer,
- REMOTE connector as interface to other Agilent products,
- analog output connector(s) for signal output, and
- interface slot for specific interfacing (external contacts, BCD, LAN and so on).

For identification and location of the connectors, see the module manual.
1 Introduction to the Preparative Pump
Agilent 1100/1200 Series Interfaces

NOTE
Never use cables other than the ones supplied by Agilent Technologies to ensure proper functionality and compliance with safety or EMC regulations.

CAN
The CAN is inter-module communication interface. It is a 2-wire serial bus system supporting high speed data communication and real-time requirement.

NOTE
If a Agilent 1100/1200 series detector (DAD/MWD/FLD/VWD/RID) is in the system, the LAN should be connected to the DAD/MWD/FLD/VWD/RID (due to higher data load). If no Agilent detector is part of the system, the LAN interface should be installed in the pump or autosampler.

LAN
The 1100/1200 modules have either an interface slot for an LAN card (e.g. Agilent G1369A LAN Interface) or they have an on-board LAN interface (e.g. detectors G1315C/D DAD and G1365C/D MWD). This interface allows the control of the module/system via a connected PC with the appropriate control software (e.g. Agilent ChemStation).

GPIB
This interface is not available in all modules and may be removed from the modules in future.

The GPIB connector is used to connect the module with a computer. The address and control switches next to the GPIB connector determine the GPIB address of your module. The switches are preset to a default address and recognized by the operating software from Agilent Technologies.

RS-232C (Serial)
The RS-232C connector is used to control the module from a computer through RS-232C connection, using the appropriate software. This connector can be configured with the configuration switch module next to the GPIB connector.
The RS-232C is designed as DCE (data communication equipment) with a 9-pin male SUB-D type connector. The pins are defined as:

### Analog Signal Output

The analog signal output (e.g. detector signal or pump pressure signal) can be distributed to a recording device. For details refer to the description of the main board of the module.

### APG Remote

The APG Remote connector may be used in combination with other analytical instruments from Agilent Technologies if you want to use features as common shut down, prepare, and so on.

Remote control allows easy connection between single instruments or systems to ensure coordinated analysis with simple coupling requirements.

The subminiature D connector is used. The module provides one remote connector which is inputs/outputs (wired-or technique).

To provide maximum safety within a distributed analysis system, one line is dedicated to SHUT DOWN the system’s critical parts in case any module detects a serious problem. To detect whether all participating modules are switched on or properly powered, one line is defined to summarize the POWER ON state of all connected modules. Control of analysis is maintained...
by signal readiness READY for next analysis, followed by START of run and optional STOP of run triggered on the respective lines. In addition PREPARE and START REQUEST may be issued. The signal level are defined as:

- standard TTL levels (0 V is logic true, + 5 V is false)
- fan-out is 10,
- input load is 2.2 kOhm against + 5 V, and
- output are open collector type, inputs/outputs (wired-or technique).

**NOTE**

All common TTL circuits operate with a 5 volt power supply. A TTL signal is defined as "low" or L when between 0 V and 0.8 V and "high" or H when between 2.0 V and 5 V (with respect to the ground terminal).

Special Interfaces

Some 1100/1200 modules have module specific interfaces/connectors. They are described in the module documentation.
1 Introduction to the Preparative Pump
Agilent 1100/1200 Series Interfaces
2 Site Requirements and Specifications

Site Requirements
  Power Consideration
  Power Cords
  Bench Space
  Environment

PhysicalSpecifications

Performance Specifications
Site Requirements

A suitable environment is important to ensure optimum performance of the instrument.

Power Consideration

The module power supply has wideranging capability (see Table 4 on page 27). It accepts any line voltage in the range described in the above mentioned table. Consequently there is no voltage selector in the rear of the module. There are also no externally accessible fuses, because automatic electronic fuses are implemented in the power supply.

**WARNING**

Incorrect line voltage at the instrument

Shock hazard or damage of your instrumentation can result, if the devices are connected to a line voltage higher than specified.

➔ Connect your instrument to the specified line voltage.

**WARNING**

Module is partially energized when switched off, as long as the power cord is plugged in.

Repair work at the module can lead to personal injuries, e.g. shock hazard, when the cover is opened and the module is connected to power.

➔ Remove the power cable from the instrument before opening the cover.

➔ Do not connect the power cable to the Instrument while the covers are removed.
CAUTION

Un accessible power plug.

In case of emergency it must be possible to disconnect the instrument from the power line at any time.

➔ Make sure the power connector of the instrument can be easily reached and unplugged.

➔ Provide sufficient space behind the power socket of the instrument to unplug the cable.

Power Cords

Different power cords are offered as options with the module. The female end of all power cords is identical. It plugs into the power-input socket at the rear of the module. The male end of each power cord is different and designed to match the wall socket of a particular country or region.

WARNING

The absence of ground connection and the use of an unspecified power cord can lead to electric shock or short circuit.

Electric Shock

➔ Never operate your instrumentation from a power outlet that has no ground connection.

➔ Never use a power cord other than the Agilent Technologies power cord designed for your region.

WARNING

Use of unsupplied cables

Using cables not supplied by Agilent Technologies can lead to damage of the electronic components or personal injury.

➔ Never use cables other than the ones supplied by Agilent Technologies to ensure proper functionality and compliance with safety or EMC regulations.
2 Site Requirements and Specifications

Site Requirements

Bench Space

The module dimensions and weight (see Table 4 on page 27) allow to place the module on almost any laboratory bench. It needs an additional 2.5 cm (1.0 inches) of space on either side and approximately 8 cm (3.1 inches) in the rear for the circulation of air and electric connections.

If the bench should carry a complete Agilent 1200 Series system, make sure that the bench is designed to carry the weight of all the modules.

NOTE

The module should be operated in a horizontal position!

For a complete system including multiple pumps, it is recommended to position the modules in two or more stacks.

Environment

Your module will work within specifications at ambient temperatures and relative humidity as described in Table 4 on page 27.

CAUTION

Condensation within the module

Condensation will damage the system electronics.

⇒ Do not store, ship or use your module under conditions where temperature fluctuations could cause condensation within the module.

⇒ If your module was shipped in cold weather, leave it in its box and allow it to warm slowly to room temperature to avoid condensation.

Unpacking the Preparative Pump

Damaged Packaging

Upon receipt of your quaternary pump, inspect the shipping containers for any signs of damage. If the containers or cushioning material are damaged, save them until the contents have been checked for completeness and the quaternary pump has been mechanically and electrically checked. If the shipping container or cushioning material is damaged, notify the carrier and save the shipping material for the carrier's inspection.

Delivery Checklist

Ensure all parts and materials have been delivered with the preparative pump. The delivery checklist is shown in Table 6 on page 31 till Table 9 on page 33. To aid in parts identification, please see “Parts and Materials for Maintenance” on page 133. There are two different kits that can possibly be delivered with the pump:

1. A *Basis kit (G1361-68708)* is delivered with every isocratic configuration or if the pump is the first pump in a system (isocratic configuration, order No. G1361A).

2. A *Gradient kit (G1361-68707)* is delivered with every additional pump that is added to a system’s first pump (gradient configuration, order No. G1391A).

Please report missing or damaged parts to your local Agilent Technologies sales and service office.

If your preparative pump is part of a complete Agilent 1200 Series system, you can ensure optimum performance and minimum delay volume by installing the following configuration.

- Figure 5 on page 34 and Figure 6 on page 35 show the configuration recommended for the pump in a UV based system.
NOTE
For information about connecting an LC-MSD or a None-1200 Series detector to the system, please refer to the “User’s Guide for Purification / High Throughput System”, PN G2262-90010 or to the “Installation Note for the Mass Based Fraction Collection Kit”.

![Recommended Stack Configuration - Preparative System (Rear View)](image)

Figure 6  Recommended Stack Configuration - Preparative System (Rear View)

NOTE
If a G1330B ALS thermostat is part of the system it must always be installed underneath the Autosampler.

Preparations

- Locate bench space.
- Provide power connections.
- Unpack the pump.

**WARNING**

*Instrument is partially energized when switched off*

The power supply still uses some power, even if the power switch on the front panel is turned off.

➡️ To disconnect the module from line, unplug the power cord.

**WARNING**

Use of unsupplied cables

Using cables not supplied by Agilent Technologies can lead to damage of the electronic components or personal injury.

➡️ Never use cables other than the ones supplied by Agilent Technologies to ensure proper functionality and compliance with safety or EMC regulations.
"Defective on arrival" problems

If there are signs of damage, please do not attempt to install the module. Inspection by Agilent is required to evaluate if the instrument is in good condition or damaged.

➔ Notify your Agilent sales and service office about the damage.

➔ An Agilent service representative will inspect the instrument at your site and initiate appropriate actions.

1. Place the module on the bench in a horizontal position.
2. Ensure the power switch on the front of the preparative pump is OFF (switch stands out).
3. At the rear of the preparative pump move the security lever to its maximum right position.

![Front View of the Preparative Pump](image)
3 Installing the Pump
Installing the Preparative Pump

4 Connect the power cable to the power connector at the rear of the module (see Figure 8 on page 38).

5 If required, connect additional interface and control cables to the preparative pump (Figure 9 on page 38). See also “Connecting Modules and Control Software” on page 40.
The CAN bus is a serial bus with high-speed data transfer. The two connectors for the CAN bus are used for internal Agilent 1200 Series module data transfer and synchronization.

The REMOTE connector may be used in combination with other analytical instruments from Agilent Technologies if you want to use features such as common shut down, prepare, and so on.

The RS-232 connector may be used to control the preparative pump from a computer through an RS-232 connection, using appropriate software. This connector needs to be activated by the 8-bit configuration switch module in the upper right corner of the rear of the pump. The software needs the appropriate drivers to support this communication. See your software documentation for further information.

The power input socket accepts a line voltage of 100 – 240 Volts AC ± 10 % with a line frequency of 50 - 60 Hz. max. power consumption is 250 VA (Volt-Amps). There is no voltage selector on your preparative pump because the power supply has wide-ranging capability. There are no externally accessible fuses. The security lever at the power input socket prevents that the preparative pump cover is taken OFF when line power is still connected.

The interface (BCD) board slot is used for external contacts, BCD output and for LAN communication.

The CAN-DC-out provides 24 Volts DC power for external CAN devices like a switch valve. Max. permanent power consumption is 100 mA/channel or 2 A for 2 sec.
Connecting Modules and Control Software

**WARNING**

Use of unsupplied cables

Using cables not supplied by Agilent Technologies can lead to damage of the electronic components or personal injury.

➔ Never use cables other than the ones supplied by Agilent Technologies to ensure proper functionality and compliance with safety or EMC regulations.

Connecting Agilent 1200 Series modules

1. Place the individual modules in a stack configuration as shown in Figure 5 on page 34.

2. Ensure the power switches on the front of the modules are OFF (switches stand out).

3. Plug a CAN cable into the CAN connector at the rear of the respective module (except vacuum degasser).

4. Connect the CAN cable to the CAN connector of the next module, see Figure 6 on page 35.

5. Press in the power switches to turn on the modules.
Connecting control software and/or control modules

1. Ensure the power switches on the front of the modules in the stack are OFF (switches stand out).
2. Plug a GPIB cable into the GPIB connector at one of the modules, preferably at the detector (MUST for the DAD).
3. Connect the GPIB cable to the Agilent control software in use.
4. Plug a CAN cable into the CAN connector of the control module.

**NOTE**
Do not connect the Agilent control software or the control module with the vacuum degasser.

5. Connect the CAN cable to the CAN connector of one of the modules.
6. Press in the power switches to turn on the modules.

**NOTE**
The Agilent control software (e.g. ChemStation, EZChrom, OL, etc.) can be also be connected to the system through a LAN cable, which requires the installation of a LAN-board. For more information about connecting the control module or Agilent control software refer to the respective user manual. For connecting the Agilent 1200 Series equipment to non-Agilent 1200 Series equipment, see “Introduction to the Preparative Pump” on page 8.
Flow Connections for a Single (Isocratic) Preparative Pump

<td>Parts from basis kit (see Table 8 on page 32)</td>
</tr>
</tbody>
</table>

Preparations

Pump is installed in the HPLC system

**WARNING**

When opening capillary or tube fittings solvents may leak out.
The handling of toxic and hazardous solvents and reagents can hold health risks.

➔ Please observe appropriate safety procedures (for example, goggles, safety gloves and protective clothing) as described in the material handling and safety data sheet supplied by the solvent vendor, especially when toxic or hazardous solvents are used.

**WARNING**

Danger of Explosion
Pumping solvents at high flow rates generally results in electrostatic charging of the solvents, which may result in the potential ignition of flammable vapors or solvents.

➔ To avoid electrostatic discharge, never use the pump without grounded metal solvent bottles.

➔ Do not use metal bottles without appropriate grounding!
Installing the Pump

Flow Connections for a Single (Isocratic) Preparative Pump

1. Remove the front cover by pressing the snap fasteners on both sides.

![Figure 10](image) Removing the Front Cover

2. Place the solvent cabinet on top of the module.

3. Place the bottle into the solvent cabinet and place a bottle head assembly into the bottle. *Ground the solvent bottle!*

4. Connect the solvent tubes from the bottle head assemblies to the inlet adapters of the pump. Fix the tubes in the clips of solvent cabinet and preparative pump.

5. By holding a piece of sanding paper around the waste tubing connect it to the electromagnetic purge valve (EMPV) and place it into your waste system.

6. If the preparative pump is not part of an Agilent 1200 Series system stack or placed on the bottom of a stack, connect the corrugated waste tube to the waste outlet of the pump leak handling system.

**NOTE**
In order to guarantee an error-free handling of any leakage that may occur in the system, all modules of a stack must be thoroughly aligned on top of each other. Outstanding knobs at the rear of the top covers of the modules and holes as counterparts at the rear of the bottom covers of the modules will help to align the instruments nicely on top of each other by making them slide into the correct position. This will then allow any possible spills to be routed safely from one instrument to the next one with the help of the built in leak drainage system. (Each module has a funnel to catch drops coming from the above instrument, from there spills a lead through a waste drain tube into the leak pan and out from there through an outlet on to the next module).
Flow Connections for a Single (Isocratic) Preparative Pump

7 Connect the Outlet Capillary (G1361-67302) to the electromagnetic purge valve (EMPV) and make the necessary connections the other side of the capillary (normally a capillary to an injector or injection valve).

8 Install the seal wash tubings, as shown in Figure 11 on page 44. You need a tubing from your seal wash solvent bottle to the seal wash pump, one from there to the pump head and one from the pump head to waste.

9 Install the front cover.

10 Press in the power switch to turn ON the preparative pump.

Figure 11  Flow connections to the preparative pump

Preparations
- Pumps are installed in the HPLC system

WARNING
When opening capillary or tube fittings solvents may leak out.
The handling of toxic and hazardous solvents and reagents can hold health risks.

➤ Please observe appropriate safety procedures (for example, goggles, safety gloves and protective clothing) as described in the material handling and safety data sheet supplied by the solvent vendor, especially when toxic or hazardous solvents are used.

WARNING
Danger of Explosion
Pumping solvents at high flow rates generally results in electrostatic charging of the solvents, which may result in the potential ignition of flammable vapors or solvents.

➤ To avoid electrostatic discharge, never use the pump without grounded metal solvent bottles.

➤ Do not use metal bottles without appropriate grounding!
3 Installing the Pump
Flow Connections for a Dual (Binary Gradient) Preparative Pump

1 Remove the front covers of both pumps by pressing the snap fasteners on both sides.

2 Place the solvent cabinet on top of the module.

3 Place the bottles into the solvent cabinet and place a bottle head assembly into each bottle. *Ground the solvent bottles!*

4 Connect the solvent tubes from the bottle head assemblies to the inlet adapters of the pumps. Fix the tubes in the clips of solvent cabinet and preparative pumps.

5 By holding a piece of sanding paper around the waste tubing connect it to the electromagnetic purge valve (EMPV) of each pump and place it into your waste system.

6 If one of the preparative pumps is placed on the bottom of a stack, connect the corrugated waste tube to the waste outlet of the pump leak handling system.

**NOTE**
In order to guarantee an error-free handling of any leakage that may occur in the system, all modules of a stack must be thoroughly aligned on top of each other. Outstanding knobs at the rear of the top covers of the modules and holes as counterparts at the rear of the bottom covers of the modules will help to align the instruments nicely on top of each other by making them slide into the correct position. This will then allow any possible spills to be routed safely from one instrument to the next one with the help of the built in leak drainage system. (Each module has a funnel to catch drops coming from the above instrument, from there spills a lead through a waste drain tube into the leak pan and out from there through an outlet on to the next module).
7 Connect the long capillary (300 mm, G1361-67306) to the electromagnetic purge valve (EMPV) of the upper pump and connect the female T-piece to the other end of the capillary.

8 Connect the medium length capillary (140 mm, G1361-67304) to the electromagnetic purge valve (EMPV) of the lower pump and connect the other end of the capillary to the female T-piece.

9 Install the mixer (79835-87330) in the clips on the front panel of the bottom pump.

10 Connect the capillary (G1361-67305) from the outlet of the female T-piece to the mixer.

11 Install the outlet capillary (G1361-67302) to the mixer and make the necessary connections the other side of the capillary (normally a capillary to an injector or injection valve).

12 Install the seal wash tubings, as shown in Figure 13 on page 48. You need - for each of the pumps - a tubing from your seal wash solvent bottle to the seal wash pump, one from there to the pump head and one from the pump head to waste.

13 Install the front cover.
Press in the power switch to turn ON the preparative pumps.

**Figure 13** Flow connections to the preparative pump
Get the System Ready for the First Analysis

When you are using the system for the first time it is recommended to prime it to remove all the air and the possible contamination introduced in the flow path during the installation.

Priming your preparative LC system with the pump

The pump should never be used for priming empty tubings (never let the pump run dry). Use a syringe to draw enough solvent for completely filling the tubings to the pump inlet before continuing to prime with the pump.

1 Set the flow rate to 5 ml/min and pump for 5 minutes with an open EMPV to prime your new tubings and capillaries and to remove potential air bubbles or contamination from the flow path.

2 Check your system for leak tightness with the help of the built in pressure test (see Pressure Test) (“Prep Pump Pressure Test Description” on page 94).

3 Refer to “Optimizing Performance” on page 65 for optimizing your pump’s performance.

4 Before starting an analysis pump until you receive a stable pressure signal from your pump and until your detector baseline has stabilized (normally no more than five minutes). Low %-ripple is a vital sign for a smoothly operating pump and a stable system.
5 When the pumping system has been turned OFF for a certain time (for example, overnight) repeat Step 3 (step 4 on page 49).

Using the Preparative Pump

Hints for Successful Use of the Preparative Pump  52
Solvent Information  53
Prevent Blocking of Solvent Filters  54
Algae Growth in HPLC Systems  55
    How to Prevent and/or Reduce the Algae Problem  56
Setting Up the Pump  57
    Setting up the Preparative Pump (Agilent ChemStation)  57
Hints for Successful Use of the Preparative Pump

- Flush the pump extensively, when changing to a new solvent.
- The system pressure must be higher than 20 bar at the pump outlet for optimum performance of the pump.
- Place the solvent cabinet with the solvent bottles always on top of the preparative pump (or at a higher level).
- Prevent blocking of solvent inlet filters (never use the pump without solvent inlet filters). Growth of algae should be avoided (see “Prevent Blocking of Solvent Filters” on page 54).
- Regularly clean the filter cup and the filter frit installed in the multi assembly. A back pressure greater than 10 bar, when pumping pure HPLC grade water at a flow rate of 50 ml/min while the EMPV is open indicates that one of the two filters is blocked or that the EMPV does not switch (open) properly. Make sure to follow the correct procedures for cleaning filters (see “Simple Repairs” on page 114) and the EMPV (see “Prep Pump EMPV Cleaning Description” on page 103). Always clean the pump’s filters, after exchanging seals.
- Confirm that the pump and the rest of the system are completely leak tight by performing the built in Leak-test (see “Prep Pump Leak Test Description” on page 98) and Pressure-test (see “Prep Pump Pressure Test Description” on page 94), regularly.
- When using buffer solutions, flush the system with plenty of water to remove all buffer solution from the entire system before switching it OFF or before changing to an organic solvent.
- Always use the seal wash function.
- Check the pump seals. Scratched plungers will lead to micro leaks and will decrease the lifetime of the seal plungers for scratches when changing the piston.
- For the generation of gradients in systems with multiple pump setups make sure that none of the pumps delivers less than a minimum flow rate of 5 ml/min at any time during the gradient run, in order to achieve best performance.
Solvent Information

Always filter solvents through 0.4 µm filters, small particles can permanently block the capillaries and valves. Avoid the use of the following steel-corrosive solvents:

- Solutions of alkali halides and their respective acids (for example, lithium iodide, potassium chloride, and so on).
- High concentrations of inorganic acids like sulfuric and nitric acid, especially at higher temperatures (replace, if your chromatography method allows, by phosphoric acid or phosphate buffer which are less corrosive against stainless steel).
- Halogenated solvents or mixtures which form radicals and/or acids, for example:
  
  \[ 2\text{CHCl}_3 + \text{O}_2 \rightarrow 2\text{COCl}_2 + 2\text{HCl} \]

  This reaction, in which stainless steel probably acts as a catalyst, occurs quickly with dried chloroform if the drying process removes the stabilizing alcohol.

- Chromatographic grade ethers, which can contain peroxides (for example, THF, dioxane, di-isopropylether). Such ethers should be filtered through dry aluminium oxide which adsorbs the peroxides.

- Solvents containing strong complexing agents (e.g. EDTA).

- Mixtures of carbon tetrachloride with 2-propanol or THF dissolve stainless steel.
Prevent Blocking of Solvent Filters

Contaminated solvents or algae growth in the solvent bottle will reduce the lifetime of the solvent filter and will influence the performance of the module. This is especially true for aqueous solvents or phosphate buffers (pH 4 to 7). The following suggestions will prolong lifetime of the solvent filter and will maintain the performance of the module.

- Use a sterile, if possible amber, solvent bottle to slow down algae growth.
- Filter solvents through filters or membranes that remove algae.
- Exchange solvents every two days or refilter.
- If the application permits add 0.0001-0.001M sodium azide to the solvent.
- Place a layer of argon on top of your solvent.
- Avoid exposure of the solvent bottle to direct sunlight.
- Filter HPLC grade (dry) Acetonitrile before use. The dryer the Acetonitrile, the stronger the tendency to form polymers and therefore block the system. Refilter at least every two days.

**NOTE**

Never use the system without solvent filter installed.
Algae Growth in HPLC Systems

The presence of algae in HPLC systems can cause a variety of problems that may be incorrectly diagnosed as instrument or application problems. Algae grow in aqueous media, preferably in a pH range of 4-8. Their growth is accelerated by buffers, for example phosphate or acetate. Since algae grow through photosynthesis, light will also stimulate their growth. Even in distilled water small-sized algae grow after some time.

Instrumental Problems Associated With Algae

Algae deposit and grow everywhere within the HPLC system causing:

- Deposits on ball valves, inlet or outlet, resulting in unstable flow or total failure of the pump.
- Small pore solvent inlet filters to plug, resulting in unstable flow or total failure of the pump.
- Small pore high pressure solvent filters, usually placed before the injector to plug resulting in high system pressure.
- Column filters to plug giving high system pressure.
- Flow cell windows of detectors to become dirty resulting in higher noise levels (since the detector is the last module in the flow path, this problem is less common).

Symptoms Observed with the Agilent 1200 Series HPLC

In contrast to the HP 1090 and HP 1050 Series HPLC systems which use helium degassing, algae have a better chance to grow in systems such as the Agilent 1200 Series where helium is not used for degassing (most algae need oxygen and light for growth).

The presence of algae in the Agilent 1200 Series can cause the following to occur:

- Short lifetime of solvent filters (bottle head assembly). A blocked solvent filter in the bottle, especially when only partly blocked, is more difficult to identify and may show up as gradient performance problems, intermittent pressure fluctuations etc.
Algae growth may also be the possible source for failures of the ball valves and other components in the flow path.

How to Prevent and/or Reduce the Algae Problem

- Always use freshly prepared solvents, especially use demineralized water which was filtered through about 0.2 μm filters.
- Never leave mobile phase in the instrument for several days without flow.
- Always discard “old” mobile phase.
- Use the amber solvent bottle (part number 9301-1450) supplied with the instrument for your aqueous mobile phase.
- If possible add a few mg/l sodium azide or a few percent organic solvent to the aqueous mobile phase.
Setting Up the Pump

Setting up the Preparative Pump (Agilent ChemStation)

The Agilent 1200 Series Preparative Pump can be operated as Isocratic Pump or can be combined with an additional pump to form a gradient system. Details for both pump configurations are explained in “Flow Connections for a Single (Isocratic) Preparative Pump” on page 42 for the isocratic pump and in “Flow Connections for a Dual (Binary Gradient) Preparative Pump” on page 45 for the gradient pump.

If the Agilent ChemStation software is started, all pumps that are connected to the LC system are recognized and can be added to the list of configured modules (see Figure 14 on page 57). If two pumps are configured, they are treated as preparative gradient pump. The first (upper) pump in the configuration will deliver solvent A and the second (lower) pump will deliver solvent B.

![Figure 14 List of Configured Modules](image-url)
4 Using the Preparative Pump
Setting Up the Pump

The parameters for setting up the preparative pump can be accessed through the instrument menu or by clicking on the pump icon in the system diagram (see Figure 15 on page 58).

![Figure 15 System Diagram](image)

The Setup dialog box depends on the configuration of the pump. In Figure 16 on page 58 you see the dialog box for the isocratic pump and in Figure 17 on page 59 you see the interface for the gradient pump.

![Figure 16 Setup dialog box (isocratic pump)](image)
In these dialog boxes you can specify the following parameters:

Flow: Flow rate delivered by the pump. For gradient systems the flow parameter defines the combined flow delivered by the system on channel A and B. The maximum settable flow is 100 ml/min. For best performance a flow above 5 ml/min should be chosen. The pump can be operated at lower flow rates. However a slightly higher pressure ripple will be observed. In addition the system pressure should always be kept above 20 bar.

Stop Time: The Stop Time defines the end of your analysis run. After the stop time all gradients are stopped and the pump settings return to the initial values. Typically, the Stop Time of the pump specifies the Stop Time for all other modules in the LC system.

Post Time: During the Post Time the instrument stays in the Not Ready state and delays the start of the next analysis. The Post Time allows the column to equilibrate after a gradient run.
Max Pressure: The pump shuts down when exceeding the maximum pressure limit to protect the system or the column against overpressure. The Preparative Pump can operate up to 400 bar over the entire flow range. The limit has to be changed, if columns or other components with lower pressure limits are part of the LC system.

Min. Pressure: The pump shuts down, if the pressure is below this limit for several seconds.

Purge (Solvent A): If the purge function is enabled, the purge valve (EMPV) will open for the specified time before each analysis. In this dialog box, you can only control the automated purge for pump A. If you are using a gradient system, choose Purge B to specify and enable the purge procedure on channel B (see Figure 18 on page 60).

![Purge Dialog Box](image)

**Figure 18** Purge Dialog Box

Solvent A: This text field allows you to write down a brief description of solvent A.

Solvent B: This text field allows you to write down a brief description of solvent B on gradient systems. In addition, you can specify the initial proportion of solvent B in %. This composition is valid as soon as the pump is switched on, before the run and after the Stop Time. During the run the composition (gradient) can be specified with the timetable.

Timetable: With the timetable you can specify changes of the composition (%B), the flow and the maximum pressure limit during the run. It is used to define solvent gradients. The composition %B is only available on gradient systems.
Flow Ramp and Compressibility can be specified in the Auxiliary dialog box (see Figure 19 on page 61).

Flow Ramp: This is the rate for turning the flow up and down, when the pump is switched on or off. The default setting (800 ml/min/min) protects the column against sudden pressure peaks and drops.

Compressibility: The compressibility of the solvent has to be specified in this field. The value will be used for the compressibility compensation to optimize the performance of the pump. For more details read the chapter “How to Optimize the Compressibility Compensation Setting” on page 67.

The Auxiliary dialog box is also available for channel B on gradient pump systems.

The Control dialog box (Figure 20 on page 62) allows you to switch the pump on or off.

Purge: In this field you can open and close the automated purge valve, or you can specify a time for how long the purge valve will be open.

Error Method: By setting an Error Method you can define a pump particular method that is run, if an instrument error is detected. It is typically used to shut down the pump in a controlled manner.
Use the Setup Pump dialog box (Figure 16 on page 58 or Figure 17 on page 59) to define a suitable error method. Then select Take Current Method and click OK. The current method is immediately copied to the pump and stored as error method and executed in case of an instrument error.

Seal Wash Pump: The settings for seal wash pump can be controlled in this section. The seal wash can be switched off or a single wash can be started for a user-specified time. In addition, you can choose to turn the seal wash on periodically for a user-defined on-time. The on-time must be between 0.1 min and 70% of the entire period.

Running the seal wash periodically will reduce the ware of the pump seals and increase the maintenance interval of your pump. For more details read the chapter “How to Configure the Seal Wash Function” on page 66.

![Control dialog box](image)

**Figure 20** Control dialog box

The Control dialog box is also available for channel B on gradient pump systems.

To prevent the pump from running dry you can specify the fillings of your solvent reservoir in the Solvent Bottle Filling dialog box (Figure 21 on page 63). This dialog box can be opened through Instrument > More Preparative pump > Bottle Filling... or by clicking on the bottle icon in the graphical user interface (Figure 14 on page 57).
Actual Volume: Set the actual volume after refilling the solvent bottle. When turning on the pump, the current filling will be calculated based on the flow rate and the run-time of the pump.

Total Volume: This value is used to calculate the % filling of the bottle for the display in the system diagram.

You can select not to start the run, if the current fill level is below a user-defined value, and to turn-off the pump before it is running out of solvent.

The Solvent Bottle Filling dialog box is also available for channel B on gradient pump systems.

How to Optimize the Compressibility Compensation Setting  67
Optimizing Performance

How to Configure the Seal Wash Function

How to Configure the Seal Wash Function

Always use the seal wash function which is delivered with your pump.

NOTE

The seal wash function cannot be operated permanently (danger of overheating). Switch on the seal wash pump in regular intervals (normally for 30 s every 30 minutes) for a certain length of time. It is however important to keep the back of the seals wet with the help of the seal wash function.

Water or Aqueous Buffer Solutions

We recommend a composition of 10% Isopropanol in HPLC grade water for water or aqueous buffer solutions. With buffer solutions, the seal wash pump should be configured such, that it is turned on for a duration of 30 s every 5 minutes (with a maximum of 30% cycle time). Shorten the intervals between the pump turn-ons for highly concentrated buffer solutions (> 0.1 M buffer solutions).

Organic Solvents

For all organic non buffered solutions, we recommend to use the same solvent for the seal wash as the one that is currently pumped by your preparative pump. In this case, the seal wash pump has to be operated in large intervals, only. Basically it is enough to keep the back of seals wet with the help of the seal wash option.

NOTE

Beware that the seal wash tubing is made of silicon. Never use any solvents for the seal wash, that are not compatible with silicone.
How to Optimize the Compressibility Compensation Setting

The compressibility compensation default settings are $75 \times 10^{-6}$ /bar (best for most aqueous solutions). Under normal conditions the default settings reduce the pressure pulsation to values (below 2% of system pressure for a complete system with a preparative scale sized column installed) that will be sufficient for most applications. If the compressibility values for the solvents used differ from the default settings, it is recommended to change the compressibility values accordingly. Compressibility settings can be optimized by using the values for various solvents described in Table 11 on page 68. If the solvent in use is not listed in the compressibility table, when using premixed solvents and if the default settings are not sufficient for your application the following procedure can be used to optimize the compressibility settings:

1. Start the preparative pump with the adequate flow rate. The system pressure should be between 50 and 150 bar.
2. Before starting the optimization procedure, the flow must be stable. Before starting the procedure, check the tightness of the system with the help of the built in pressure test (see “Prep Pump Pressure Test Description” on page 94).
3. Verify the tightness of the pump itself (piston/seal combinations, valves, filters fittings, etc.) with the help of the built in Leak Test (see “Prep Pump Leak Test Description” on page 98).
4. Your pump must be connected to a Agilent ChemStation or handheld controller, the pressure and %-ripple can be monitored with one of these instruments.
5. Starting with a compressibility setting of $50 \times 10^{-6}$ /bar increase the value in steps of 10. The compressibility compensation setting that generates the smallest pressure ripple is the optimum value for your solvent composition.
6. Repeat step 1 on page 67 through step 5 on page 67 for each preparative pump in a system with a multiple pump setup.

NOTE

Use the preparative pump with a flow rate of at least 20 ml/min.

Agilent Lab Advisor software

The Agilent Lab Advisor software is a standalone product that can be used with or without data system. Agilent Lab Advisor software helps to manage the lab for high quality chromatographic results and can monitor in real time a single Agilent LC or all the Agilent GCs and LCs configured on the lab intranet.

Agilent Lab Advisor software provides diagnostic capabilities for all Agilent 1200 Series HPLC modules. This includes tests and calibrations procedures as well as the different injector steps to perform all the maintenance routines.

A Agilent Lab Advisor software also allows users to monitor the status of their LC instruments. The Early Maintenance Feedback (EMF) feature helps to carry out preventive maintenance. In addition, users can generate a status report for each individual LC instrument. The tests and diagnostic features as provided by the Agilent Lab Advisor software may differ from the descriptions in this manual. For details refer to the Agilent Lab Advisor software help files.

This manual provides lists with the names of Not Ready messages, and other common issues.
Overview of the Pump’s Indicators and Test Functions

This chapter describes the instrument’s built in troubleshooting and test functions.

Status Indicators

The preparative pump is provided with two status indicators which indicate the operational state (prerun, run, and error states) of the preparative pump. The lower left indicates the power supply status, the upper right indicates the preparative pump status. The status indicators provide a quick visual check of the operation of the preparative pump (see “Status Indicators” on page 72).

Error Messages

In the event of an electronic, mechanical or hydraulic failure, the preparative pump generates an error message in the user interface. For details on error messages and error handling, please refer to the Agilent Lab Monitor & Diagnostic Software.

Pressure Test

The pressure test is a quick test designed to determine the pressure tightness of the system. After exchanging flow path components (e.g., pump seals or injection seal), use this test to verify the system is pressure tight up to 400 bar (see “Prep Pump Pressure Test Description” on page 94).

Leak Test

The leak test is a diagnostic test designed to determine the pressure tightness of the preparative pump. When a problem with the preparative pump is suspected, use this test to help troubleshoot the preparative pump and its pumping performance (see “Prep Pump Leak Test Description” on page 98).
Status Indicators

Two status indicators are located on the front of the preparative pump. The lower left one indicates the power supply status, the upper right one indicates the instrument status.

Power Supply Indicator

The power supply indicator is integrated into the main power switch. When the indicator is illuminated (green) the power is ON.

NOTE

The power switch stays pressed in and a green indicator lamp in the power switch is ON when the preparative pump is turned ON. When the line power switch stands out and the green light is OFF, the preparative pump is turned OFF.
Instrument Status Indicator

The instrument status indicator indicates one of four possible instrument conditions:

- When the status indicator is OFF (and power switch light is ON), the module is in aprerun condition, and is ready to begin an analysis.
- A green status indicator, indicates the module is performing an analysis (run mode).
- A yellow indicator indicates a not-ready condition. The module is in a not-ready state when it is waiting for a specific condition to be reached or completed (for example, immediately after changing a setpoint), or while a self-test procedure is running.
- An error condition is indicated when the status indicator is red. An error condition indicates the module has detected an internal problem which affects correct operation of the module. Usually, an error condition requires attention (for example, leak, defective internal components). An error condition always interrupts the analysis.
- A flashing yellow status indicator indicates that the module is in its resident mode. Call your local service provider for assistance upon observing this error condition.
- A flashing red status indicator indicates a severe error during the startup procedure of the module. Call your local service provider for assistance upon observing this error condition.
Depending on the User Interface, the available tests vary. Some descriptions are only available in the Service Manual.

**Table 12**  Test Functions available vs. User Interface

</tbody>
</table>
Error Messages

Error messages are displayed in the user interface when an electronic, mechanical, or hydraulic (flow path) failure occurs which requires attention before the analysis can be continued (for example, repair, frit exchange or exchange of consumables required). In the event of such a failure, the red status indicator at the front of the module is switched on, and an entry is written into the instrument logbook.

Timeout

The timeout threshold was exceeded.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 The analysis was completed successfully, and the timeout function switched off the module as requested.</td>
<td>Check the logbook for the occurrence and source of a not-ready condition. Restart the analysis where required.</td>
</tr>
<tr>
<td>2 A not-ready condition was present during a sequence or multiple-injection run for a period longer than the timeout threshold.</td>
<td>Check the logbook for the occurrence and source of a not-ready condition. Restart the analysis where required.</td>
</tr>
</tbody>
</table>
**Troubleshooting and Diagnostics**

**Error Messages**

**Shut-Down**
An external instrument has generated a shut-down signal on the remote line.
The module continually monitors the remote input connectors for status signals. A LOW signal input on pin 4 of the remote connector generates the error message.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  Leak detected in another module with a CAN connection to the system.</td>
<td>Fix the leak in the external instrument before restarting the module.</td>
</tr>
<tr>
<td>2  Leak detected in an external instrument with a remote connection to the system.</td>
<td>Fix the leak in the external instrument before restarting the module.</td>
</tr>
<tr>
<td>3  Shut-down in an external instrument with a remote connection to the system.</td>
<td>Check external instruments for a shut-down condition.</td>
</tr>
</tbody>
</table>

**Remote Timeout**
A not-ready condition is still present on the remote input.
When an analysis is started, the system expects all not-ready conditions (e.g. a not-ready condition during detector balance) to switch to run conditions within one minute of starting the analysis. If a not-ready condition is still present on the remote line after one minute the error message is generated.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  Not-ready condition in one of the instruments connected to the remote line.</td>
<td>Ensure the instrument showing the not-ready condition is installed correctly, and is set up correctly for analysis.</td>
</tr>
<tr>
<td>2  Defective remote cable.</td>
<td>Exchange the remote cable.</td>
</tr>
<tr>
<td>3  Defective components in the instrument showing the not-ready condition.</td>
<td>Check the instrument for defects (refer to the instrument’s reference documentation).</td>
</tr>
</tbody>
</table>
Synchronization Lost

During an analysis, the internal synchronization or communication between one or more of the modules in the system has failed.

The system processors continually monitor the system configuration. If one or more of the modules is no longer recognized as being connected to the system, the error message is generated.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
</table>
| 1  CAN cable disconnected. | • Ensure all the CAN cables are connected correctly.  
• Ensure all CAN cables are installed correctly. |
| 2  Defective CAN cable. | Exchange the CAN cable. |
| 3  Defective main board in a different module. | Switch off the system. Restart the system, and determine which module or modules are not recognized by the system. |
Leak

A leak was detected in the module.

The signals from the two temperature sensors (leak sensor and board-mounted temperature-compensation sensor) are used by the leak algorithm to determine whether a leak is present. When a leak occurs, the leak sensor is cooled by the solvent. This changes the resistance of the leak sensor which is sensed by the leak-sensor circuit on the main board.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Loose fittings.</td>
<td>Ensure all fittings are tight.</td>
</tr>
<tr>
<td>3. Loose or leaking active inlet valve, outlet ball valve, or EMPV.</td>
<td>Ensure pump components are seated correctly. If there are still signs of a leak, exchange the appropriate seal (active inlet valve, outlet ball valve, or EMPV).</td>
</tr>
<tr>
<td>4. Defective pump seals.</td>
<td>Exchange the pump seals.</td>
</tr>
</tbody>
</table>

Leak Sensor Open

The leak sensor in the module has failed (open circuit).

The current through the leak sensor is dependent on temperature. A leak is detected when solvent cools the leak sensor, causing the leak-sensor current to change within defined limits. If the current falls outside the lower limit, the error message is generated.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Leak sensor not connected to the main board.</td>
<td>Ensure the leak sensor is connected correctly.</td>
</tr>
<tr>
<td>2. Defective leak sensor.</td>
<td>Exchange the leak sensor.</td>
</tr>
</tbody>
</table>
**Leak Sensor Short**

The leak sensor in the module has failed (short circuit).

The current through the leak sensor is dependent on temperature. A leak is detected when solvent cools the leak sensor, causing the leak-sensor current to change within defined limits. If the current increases above the upper limit, the error message is generated.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  Defective leak sensor.</td>
<td>Exchange the leak sensor.</td>
</tr>
<tr>
<td>2  Leak sensor incorrectly routed, being pinched by a metal component.</td>
<td>Exchange the leak sensor.</td>
</tr>
</tbody>
</table>

**Compensation Sensor Open**

The ambient-compensation sensor (NTC) on the main board in the module has failed (open circuit).

The resistance across the temperature compensation sensor (NTC) on the main board is dependent on ambient temperature. The change in resistance is used by the leak circuit to compensate for ambient temperature changes. If the resistance across the sensor increases above the upper limit, the error message is generated.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  Defective main board.</td>
<td>Exchange the main board.</td>
</tr>
</tbody>
</table>
Compensation Sensor Short

The ambient-compensation sensor (NTC) on the main board in the module has failed (short circuit).

The resistance across the temperature compensation sensor (NTC) on the main board is dependent on ambient temperature. The change in resistance is used by the leak circuit to compensate for ambient temperature changes. If the resistance across the sensor falls below the lower limit, the error message is generated.

Probable cause | Suggested actions
--- | ---
1 Defective main board. | Exchange the main board.

Fan Failed

The cooling fan in the module has failed.

The hall sensor on the fan shaft is used by the main board to monitor the fan speed. If the fan speed falls below a certain limit for a certain length of time, the error message is generated.

Probable cause | Suggested actions
--- | ---
1 Fan cable disconnected. | Ensure the fan is connected correctly.
2 Defective fan. | Exchange fan.
3 Defective main board. | Exchange the main board.
4 Improperly positioned cables or wires obstructing fan blades. | Ensure the fan is not mechanically blocked.
Open Cover (Safety)

Do not remove instrument covers when operating. Before the instrument is switched ON, all protective earth terminals, extension cords, auto-transformers, and devices connected to it must be connected to a protective earth via a ground socket. Any interruption of the protective earth grounding will cause a potential shock hazard that could result in serious personal injury. Whenever it is likely that the protection has been impaired, the instrument must be made inoperative and be secured against any intended operation.

**WARNING**

Open main cover

The following procedures require opening the main cover of the instrument.

➔ Always ensure the instrument is disconnected from the line power when the main cover is removed.

➔ The security lever at the power input socket prevents that the instrument cover is taken off when line power is still connected.

**WARNING**

Module is partially energized when switched off, as long as the power cord is plugged in.

Repair work at the module can lead to personal injuries, e.g. shock hazard, when the cover is opened and the module is connected to power.

➔ Make sure that it is always possible to access the power plug.

➔ Remove the power cable from the instrument before opening the cover.

➔ Do not connect the power cable to the Instrument while the covers are removed.
Open Cover

The top foam has been removed.

The sensor on the main board detects when the top foam is in place. If the foam is removed, the pump is turned OFF within 4s for safety reasons, and the error message is generated. If the pump is started without cover, this error message is also generated and the pump is not turned on.

Probable cause | Suggested actions
---|---
1. The top foam was removed during operation or pump started without cover. | Reinstall the top foam.
2. Foam not activating the sensor. | Replace the top foam.
4. Rear of the module is exposed to strong direct sunlight. | Ensure that the rear of module is not directly exposed to strong sunlight.

Pressure Above Upper Limit

The system pressure has exceeded the upper pressure limit. This error condition automatically results in the opening of the purge valve.

Probable cause | Suggested actions
---|---
1. Upper pressure limit set too low. | Ensure the upper pressure limit is set to a value suitable for the analysis.
2. Blockage in the flowpath (after the pressure sensor). | Check for blockage in the flowpath.
3. Defective pressure sensor. | Exchange the Multi Assembly.
4. Defective main board. | Exchange the main board.
### Pressure Below Lower Limit

The system pressure has fallen below the lower pressure limit.

**Probable cause** | **Suggested actions**
---|---
1. Lower pressure limit set too high. | Ensure the lower pressure limit is set to a value suitable for the analysis.
3. Leak. | • Inspect the pump head, capillaries and fittings for signs of a leak.
   | • Purge the module. Run a pressure test to determine whether the seals or other module components are defective.
4. Defective pressure sensor. | Exchange the Multi Assembly.
5. Defective main board. | Exchange the main board.

### Pressure Sensor not Connected

The pressure readings, read by the pump ADC (analog-digital converter), are missing.

The ADC reads the pressure readings from the pressure sensor every 1 ms. If the readings are missing for longer than 10 seconds, the error message is generated.

**Probable cause** | **Suggested actions**
---|---
1. Pressure sensor not connected (should be connected to P29 on the PPM board) or connected to the seal wash cable connector (P23). | Ensure the pressure sensor connector is clean, connected and seated correctly.
3. Defective PPM board. | Exchange the PPM board.
Wrong Data from Pressure Sensor

The pressure sensor delivers readings within the range of -5 to -25 bar.

Probable cause | Suggested actions
---|---
1 Defective pressure sensor. | Exchange the pressure sensor.  
2 Defective PPM board. | Exchange the PPM board.  

Motor Drive Temperature too High

The temperature of the motor-drive circuits is too high.

The processor continually monitors the temperature of the drive circuits on the PPM board. If excessive current is being drawn for long periods, the temperature of the circuits increase. If the temperature exceeds the upper limit of 95 °C, the error message is generated.

Probable cause | Suggested actions
---|---
1 High friction (partial mechanical blockage) in the pump drive assembly. | Remove the pump head assembly. Ensure there is no mechanical blockage of the pump head assembly or pump drive assembly.  
2 Partial blockage of the flowpath in front of the pressure sensor. | • Ensure the outlet valve is not blocked.  
| | • Ensure the capillaries and frits between the pump head and pressure sensor (at the rear of the multi assembly) are free from blockage. Clean the filters in the multi assembly.  
3 Defective drive assembly. | Exchange defective drive assembly.  
4 Defective PPM board. | Exchange the PPM board.
**Motor Drive Fault**

The motor drive chip has issued a fault signal. The current drawn by the pump motor exceeded the maximum limit or under voltage lockout.

Blockages in the flowpath are usually detected by the pressure sensor, which result in the preparative pump switching OFF when the upper pressure limit is exceeded. If a blockage occurs before the pressure sensor (i.e. the pressure increase cannot be detected by the pressure sensor), the preparative pump will continue to pump. As pressure increases, the pump drive draws more current. When the current reaches the maximum limit, the preparative pump is switched OFF, and the error message is generated.

**Probable cause**

1. Flow path blockage in front of the pressure sensor.
2. Blocked outlet ball valve.
3. High friction (partial mechanical blockage) in the drive assembly.
4. Defective drive assembly.
5. Defective PPM board.

**Suggested actions**

1. Ensure the capillaries and frits between the pump head and pressure sensor (at the rear of the multi assembly) are free from blockage. Clean the filters in the multi assembly.
2. Exchange the outlet ball valve.
3. Remove the pump head assembly. Ensure there is no mechanical blockage of the pump head assembly or drive assembly.
4. Exchange the drive assembly.
5. Exchange the PPM board.
Motor Maximum Power Fault

The motor control has determined that the set maximum for the motor power was exceeded for longer than 1 second. To protect the circuitry from damage this error event is issued in this case.

Blockages in the flowpath are usually detected by the pressure sensor in the multi assembly, which results in the preparative pump switching OFF when the upper pressure limit is exceeded. If a blockage occurs before the pressure sensor (i.e. the pressure increase cannot be detected by the pressure sensor), the preparative pump will continue to pump. As pressure increases, the pump drive draws more current. When the current reaches the maximum limit, the preparative pump is switched OFF, and the error message is generated.

Probable cause

1. Flow path blockage in front of the pressure sensor.
2. Blocked outlet ball valve.
3. High friction (partial mechanical blockage) in the drive assembly.
4. Defective drive assembly.
5. Defective PPM board.

Suggested actions

1. Ensure the capillaries and frits between the pump head and pressure sensor (at the rear of the multi assembly) are free from blockage. Clean the filters in the multi assembly.
2. Exchange the outlet ball valve.
3. Remove the pump head assembly. Ensure there is no mechanical blockage of the pump head assembly or drive assembly.
4. Exchange the drive assembly.
5. Exchange the PPM board.

Motor Direction

The motor control has determined that the motor turns in opposite direction.

Probable cause

1. Cables connected in wrong orientation after a repair.

Suggested actions

Ensure the cables are correctly connected (on the main board and at the pump drive) and reconnect with new orientation, if necessary.
Pump Off While Analysis
This error message is generated, if the pump was turned OFF, during an analysis (Power OFF or pump in a Not-Ready condition).

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Power OFF or pump in a Not-Ready condition.</td>
<td>• Turn ON the Pump.</td>
</tr>
<tr>
<td></td>
<td>• Eliminate the cause of the Not-Ready condition.</td>
</tr>
</tbody>
</table>

Index Missing
The pump motion control expects one index signal for every turn of the drive wheel. The error message is generated, if this signal is not received within one complete turn of the drive wheel.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Defective or disconnected index cable.</td>
<td>Ensure the connector connected and seated correctly.</td>
</tr>
<tr>
<td>2 Defective Pump drive defective index board on pump drive.</td>
<td>Exchange the pump drive assembly.</td>
</tr>
<tr>
<td>3 Defective main board.</td>
<td>Exchange the main board.</td>
</tr>
</tbody>
</table>

Position Error
The motion control of the pump drive could not reach the desired condition within a certain time frame. The deviation from the desired position exceeded the error limit.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Blocked flow path.</td>
<td>Ensure that there is no blockage in the flow path before the pressure sensor.</td>
</tr>
<tr>
<td>2 Mechanical blockage of the pump drive assembly.</td>
<td>Exchange the pump drive assembly.</td>
</tr>
</tbody>
</table>
**Spurious Index**

The pump motion control expects one (and only one) index signal for every turn of the drive wheel. This error message is generated, if this signal is received more often than within one complete turn of the drive wheel.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  Missing reflections to light switch because of contamination on drive wheel.</td>
<td>Ensure the drive wheel is clean.</td>
</tr>

<tr>
<td>2 Leak.</td>
<td>Check for leaks with the help of the built in pressure or leak test and correct them, where necessary.</td>
</tr>
</tbody>
</table>

### Composition Cluster Partner Lost

Communication to a composition cluster partner was interrupted.

In a gradient system, two (or more) isocratic preparative pumps can be linked together in a cluster acting as one gradient pump. The error message is generated, if the communication between the partners of a cluster is interrupted.

<table>
<thead>
<tr>
<th>Probable cause</th>
<th>Suggested actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Composition cluster partner was turned OFF.</td>
<td>Turn ON composition cluster partner.</td>
</tr>
<tr>
<td>2 CAN-cable to composition cluster partner disconnected.</td>
<td>Reconnect or replace CAN-cable.</td>
</tr>
<tr>
<td>3 Defective CAN-bus.</td>
<td>Replace PPM main board.</td>
</tr>
</tbody>
</table>
**Solvent Counter Zero**

The volume counter for the bottle filling reached zero.

**Probable cause**

1. Value for bottle filling set incorrectly.
2. Solvent bottle empty.

**Suggested actions**

1. Reset bottle filling to the correct value.
2. Refill solvent bottle.

**No Motor Motion**

No motor rotation feedback.

**Probable cause**

1. Defective or disconnected index cable.
2. Encoder cable not connected at the encoder.
3. Motor defective or not connected.
4. Defective main board.

**Suggested actions**

1. Ensure the connector connected and seated correctly.
2. Ensure the encoder cable is connected and seated correctly at the encoder.
3. Exchange the pump drive assembly.
4. Exchange the main board.

**Seal Wash Current Low**

The current sensing of the seal wash motor was lower than expected.

**Probable cause**

1. Defective or disconnected seal wash pump motor.
2. Defective main board.

**Suggested actions**

- Ensure the cable is correctly connected.
- Exchange the seal wash pump motor.
- Exchange main board.
Seal Wash (Safety)

Pressure sensor incorrectly plugged into the main board port
You risk permanent damage of the pressure sensor, if the seal wash pump is turned ON while the pressure sensor is incorrectly connected to the main board port, dedicated for the seal wash pump. This requires exchange of complete multi assembly.

➔ Never turn on the seal wash pump, while the pressure sensor is connected to the main board port.
➔ Make sure the seal wash cable and the pressure sensor cable are plugged in the correct positions before turning ON the seal wash pump.

Seal Wash
This error message is generated, if the pressure sensor is incorrectly plugged into the connector on the main board, that should hold the seal wash motor cable.

Probable cause
1 Pressure sensor and seal wash pump connector were connected to the wrong position on the main board (identical connectors allow to plug into the wrong positions by mistake).

Suggested actions
Switch the connectors of the seal wash pump cable and the pressure sensor to meet the correct positions (P23 for seal wash cable, P29 for the pressure sensor cable from the multi assembly).

Wait for Encoder Position Timed Out
Encoder position was not reached within specified time.

Probable cause
1 Flow too low.

2 Pump OFF.

Suggested actions
Recalculate flow or wait time, to allow to reach encoder position before encoder position time-out.

Turn ON pump.
24V Supply for External Devices Low

Voltage sensing of the 24 Volts CAN outlet shows low voltage, probably fuse has blown.

<table>

</tbody>
</table>
Pressure Test

Prep Pump Pressure Test Description

The pressure test is a quick, built-in test designed to demonstrate the pressure-tightness of the system. The test involves monitoring the flow rate, required to keep a constant pressure of 350 bar, as the preparative pump runs through a predefined pumping sequence. The resulting flow rate provides information about the pressure tightness of the system.

Step 1

The test begins with an automated flushing of the pump at a flow rate of 25 ml/min with an open EMPV.

Step 2

The EMPV is closed and next, piston A begins pumping solvent with a flow rate of 0.5 ml/min until reaching a pressure of 150 bar. At this point, the pump delivers at a flow rate of 0.2 ml/min until reaching a pressure of 250 bar. The pump then delivers at a flow rate of 0.1 ml/min until reaching a pressure of 345 bar, then switches into its “Keep pressure mode”.

NOTE

To test the pressure tightness of all individual components in the flow path of the pump itself use the leak test, see “Prep Pump Leak Test Description” on page 98.

Step 3

When the system pressure reaches 350 bar, the preparative pump switches to its “Keep-pressure-mode”. The flow rate to compensate for leaks should from this point onwards be no more than 10 µl/minute.
Positioning the Blank Nut

If a specific component is suspected of causing a system leak, place the blank nut immediately before the suspected component, then run the pressure test again. If the test passes, the defective component is located after the blank nut. Confirm the diagnosis by placing the blank nut immediately after the suspected component. The diagnosis is confirmed if the test fails.
6 Troubleshooting and Diagnostics

Pressure Test

Running the Pressure Test

When

If problems with small leaks are suspected After maintenance of flow-path components (e.g. pump seals, injection seal) to prove pressure tightness up to 350 bar.

Tools required

• ¼-inch” wrench

Parts required

<table>
<thead>
<tr>
<th>#</th>
<th>Part number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>01080-83202</td>
<td>Blank nut</td>
</tr>
<tr>
<td></td>
<td></td>
<td>500 ml Isopropanol</td>
</tr>
</tbody>
</table>

Preparations

• Thoroughly flush the entire system with Isopropanol and remove all contaminations and potential air bubbles, release the pressure in the system and position the blank nut

NOTE

Make absolutely sure that all parts of the flow path that are part of the test are very thoroughly flushed with IPA before starting to pressurize the system! Any trace of other solvents or the smallest air bubble inside the flow path definitely will cause the test to fail!

1 Select the pressure test from the test selection menu.
2 Start the test and follow the instructions.

NOTE

Finishing the test will release the pressure in the system.

3 Remove the blanking nut after finishing the test and reconnect all capillaries.

NOTE

For detailed instructions refer to the Agilent LMD Tool.
Evaluating the Results

The sum of all leaks between the pump and the blank nut will be indicated by flow rate of > 10 µl/minute to keep the pressure constant. Note that small leaks may cause the test to fail, but solvent may not be seen leaking from a module.

**NOTE**

Please notice the difference between an *error* in the test and a *failure* of the test! An *error* means that during the operation of the test there was an abnormal termination. If a test *failed*, this means that the results of the test where not within the specified limits.

**NOTE**

Do not overtighten fittings! After the first major increase of resistance when tightening a previously loose fitting, the fitting should not be tightened any further than an additional 1/8 to 1/4 wrench turn.

**NOTE**

Often it is only a damaged blank nut itself (poorly shaped from overtightening) that causes a failure of the test. Before investigating on any other possible sources of failure make sure that the blank nut you are using is in good condition and properly tightened!

Large internal leaks at the EMPV can easily be identified by observing a flow out through the waste tubing of the EMPV, while the EMPV should be closed.
Leak Test

Prep Pump Leak Test Description

The leak test is a quick, built-in test designed to demonstrate the pressure-tightness of the pump. The test involves monitoring the pump drive steps needed to build up a pressure of 350 bar and the flow rate, required to keep a constant pressure of 350 bar, as the preparative pump runs through a predefined pumping sequence. The resulting flow rate provides information about the pressure tightness of the pump. Each step is separately performed and evaluated separately for piston 1 and piston 2.

Step 1

The test begins with an automated flushing of the pump at a flow rate of 25 ml/min with an open EMPV.

Step 2

The EMPV is closed and next, piston 1 begins pumping solvent with a flow rate of 2 ml/min until reaching a pressure of 150 bar, then the pump delivers at a flow rate of 0.2 ml/min until reaching a pressure of 250 bar, then the pump delivers at a flow rate of 0.1 ml/min until reaching a pressure of 345 bar, then the pump switches into its “Keep pressure mode”.

Step 3

The flow rate to compensate for leaks should from this point onwards be no more than 10 µl/minute.

Step 4

Steps 2 and 3 are automatically repeated for piston 2.
Running the Leak Test

When

- When problems with leaks are suspected, or after maintenance of flow-path components (e.g., pump seals, filters, EMPV or capillaries) to prove pressure tightness up to 350 bar

Tools required

- ¼ inch” wrench.

Parts required

<table>
<thead>
<tr>
<th>#</th>
<th>Part number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>01080-83202</td>
<td>Blank nut</td>
</tr>
<tr>
<td></td>
<td></td>
<td>500 ml Isopropanol</td>
</tr>
</tbody>
</table>

Preparations

- Thoroughly flush the pump with isopropanol and remove all contaminations and potential air bubbles, release the pressure in the system and position the blank nut,

**NOTE**

Make absolutely sure that all parts of the flow path that are part of the test are very thoroughly flushed with IPA before starting to pressurize the pump! Any trace of other solvents or the smallest air bubble inside the flow path definitely will cause the test to fail!

**NOTE**

It is recommended to run the EMPV cleaning procedure (see “Prep Pump EMPV Cleaning Description” on page 103) prior to running the Leak test, to remove any potential deposits from the EMPV valve.

1. Select the leak test from the test selection menu.
2. Start the test and follow the instructions.

**NOTE**

Detailed instructions are provided in the LMD Tool.

**NOTE**

“Evaluating the Results” on page 100 describes the evaluation and interpretation of the leak test results.
6 Troubleshooting and Diagnostics
Leak Test

Evaluating the Results

Defective or leaky components in the pump head lead to changes in the leak-test pressure plot. Typical failure modes are described below.

NOTE
Please notice the difference between an error in the test and a failure of the test! An error means that during the operation of the test there was an abnormal termination. If a test failed, this means that the results of the test were not within the specified limits.

NOTE
Often it is only the damaged blank nut itself (poorly shaped from overtightening) that causes a failure of the test. Before investigating on any other possible sources of failure make sure that the blank nut you are using is in good condition and properly tightened!

Error Limits Exceeded for One or Both of the Encoder Values and One or Both of the Maximum allowed Flow Rates in the Constant Pressure Mode

</tbody>
</table>
EMPV Cleaning

Prep Pump EMPV Cleaning Description

Depending on the application, particles can sometimes be collected in the EMPV valve. This fast cleaning routine is designed to remove such particle deposits. The routine should always be performed when the EMPV is suspected of being leaky or contaminated with particles.

NOTE

Large internal leaks at the EMPV can easily be identified by observing a flow out through the waste tubing of the EMPV, while the EMPV should be closed.

The EMPV outlet is plugged with a blank nut (01080-83202). After a short flushing routine the EMPV is closed and the pressure is increased to approximately 350 bar. Then the EMPV is opened and the pressure is released very quickly. The procedure is repeated 5 times in a sequence.
6 Troubleshooting and Diagnostics
EMPV Cleaning

Running the Cleaning Procedure

When
- When the EMPV is suspected of being leaky, or contaminated with particles

Tools required
- Wrench 7/16 inch.

Parts required

<table>
<thead>
<tr>
<th>#</th>
<th>Part number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>01080-83202</td>
<td>Blank nut</td>
</tr>
</tbody>
</table>

Preparations
- Plug the pump outlet with a blank nut (01080-83202) at EMPV outlet

1 Select EMPV Cleaning from the test selection menu.
2 Start the procedure and follow the instructions.

NOTE
Detailed instructions are provided in the Lab Advisor tool.

NOTE
Run a leak test (see “Prep Pump Leak Test Description” on page 98 after having performed the cleaning procedure, to ensure tightness of the EMPV.
3 For better removal of any left-over particles, it will help to clean the ball of the valve with an additional procedure, if the previous step did not help: Using a 7/16” wrench remove deposits by turning the holding screw of the EMPV body back and forth about 1/4 wrench turn several times.

4 Remove the blank nut.

5 Reconnect all capillaries.

- Exchanging the Optional Interface Board 131
- Replacing the Module’s Firmware 132
Introduction to Maintenance and Repair

Simple Repairs

The module is designed for easy repair. The most frequent repairs such as plunger seal change and purge valve frit change can be done from the front of the module with the module in place in the system stack.

These repairs are described in “Simple Repairs” on page 114.
Scientists and engineers develop and implement science and technology solutions to meet challenges of the future.

Environmental and Safety Guidelines

Warnings and Cautions

**WARNING** Module is partially energized when switched off, as long as the power cord is plugged in.

Repair work at the module can lead to personal injuries, e.g. shock hazard, when the cover is opened and the module is connected to power.

➔ Make sure that it is always possible to access the power plug.

➔ Remove the power cable from the instrument before opening the cover.

➔ Do not connect the power cable to the instrument while the covers are removed.

**WARNING** Sharp metal edges

Sharp-edged parts of the equipment may cause injuries.

➔ To prevent personal injury, be careful when getting in contact with sharp metal areas.

**WARNING** When opening capillary or tube fittings solvents may leak out.

The handling of toxic and hazardous solvents and reagents can hold health risks.

➔ Please observe appropriate safety procedures (for example, goggles, safety gloves and protective clothing) as described in the material handling and safety data sheet supplied by the solvent vendor, especially when toxic or hazardous solvents are used.

**CAUTION** Electrostatic discharge at electronic boards and components

Electronic boards and components are sensitive to electrostatic discharge (ESD).

➔ In order to prevent damage always use an ESD protection (for example, an ESD wrist strap) when handling electronic boards and components.
The electronics of the preparative pump will not allow operation of the preparative pump when the top cover and the top foam are removed. A safety light switch ON the main board will inhibit the operation of the preparative pump. Always operate the preparative pump with the top foam and top covers in place.
Using the ESD Strap

Electronic boards are sensitive to electrostatic discharge (ESD). In order to prevent damage, always use an ESD strap supplied in the standard accessory kit (see “Preparative Pump Basis Kit” on page 145) when handling electronic boards and components.

1. Unwrap the first two folds of the band and wrap the exposed adhesive side firmly around your wrist.

2. Unroll the rest of the band and peel the liner from the copper foil at the opposite end.

3. Attach the copper foil to a convenient and exposed electrical ground.

![Figure 23 Using the ESD Strap](image)

Cleaning the module

The module case should be kept clean. Cleaning should be done with a soft cloth slightly dampened with water or a solution of water and mild detergent. Do not use an excessively damp cloth as liquid may drip into the module.

**WARNING**

Liquid dripping into the electronic compartment of your module.

Liquid in the module electronics can cause shock hazard and damage the module.

➔ Do not use an excessively damp cloth during cleaning.

➔ Drain all solvent lines before opening any fittings.
Figure 24 on page 112 shows the main assemblies of the preparative pump. The pump heads and its parts do require normal maintenance (for example, seal exchange) and can be accessed from the front (simple repairs). Replacing internal parts will require to remove the module from its stack and to open the top cover.

Checking and Cleaning the Solvent Inlet Filters

**NOTE**
A blocked filter does not affect the pressure readings of the preparative pump. The pressure readings cannot be used to check whether the filter is blocked or not.

**NOTE**
If the filter is in good condition the solvent will freely run out of the solvent tube (due to hydrostatic pressure). If the solvent filter is partly blocked only little solvent will drip out of the solvent tube.

**WARNING**
When opening capillary or tube fittings solvents may leak out.
The handling of toxic and hazardous solvents and reagents can hold health risks.

➔ Please observe appropriate safety procedures (for example, goggles, safety gloves and protective clothing) as described in the material handling and safety data sheet supplied by the solvent vendor, especially when toxic or hazardous solvents are used.

**CAUTION**
Small particles can permanently block the capillaries and valves of the module.

Damage of the module.

➔ Always filter solvents.

➔ Never use the module without solvent inlet filter.
7 Maintenance
Simple Repairs

Cleaning the Solvent Filters

When
If solvent filter is blocked

Parts required
#  Description
1  Concentrated nitric acid (65%)
1  Bidistilled water
1  Beaker

Preparations
Remove the solvent inlet tube from the inlet valve of the pump and let the tube hang down

1  Remove the blocked solvent filter from the bottle-head assembly and place it in a beaker with concentrated nitric acid (65%) for one hour.
2  Thoroughly flush the filter with bidistilled water (remove all nitric acid, some columns can be damaged by nitric acid).
3  Replace the filter.
Exchanging the Inlet/Outlet Ball Valves

Removing an Inlet Ball Valve (Bottom of the Pump Head)

When

If internally / externally leaking (back flow)

Tools required

- Wrench 17 mm
- Wrench 1/4 inch

Parts required

<table>
<thead>
<tr>
<th>#</th>
<th>Part number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>G1361-60012</td>
<td>Valve assembly</td>
</tr>
</tbody>
</table>

NOTE

The inlet valves do not necessarily have to be replaced in pairs. Use the built in Leak Test (see “Prep Pump Leak Test Description” on page 98) to identify the valve, that is not working properly.

1 Disconnect the solvent inlet tube at the inlet valve. Beware of leaking solvents.

2 Using a 17-mm wrench loosen the inlet valve and remove the valve adapter, including the valve assembly from the pump head.

Figure 25 Ball Valve Parts
Removing an Outlet Ball Valve (Top of the Pump Head)

When
If internally / externally leaking (back flow)

Tools required
• Wrench 17 mm
• Wrench 1/4 inch

Parts required

<table>
<thead>
<tr>
<th>#</th>
<th>Part number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>G1361-60012</td>
<td>Valve assembly</td>
</tr>
</tbody>
</table>

NOTE
The outlet valves do not necessarily have to be replaced in pairs. Use the built in Leak Test (see “Prep Pump Leak Test Description” on page 98) to identify the valve, that is not working properly.

1 Disconnect the solvent outlet capillary at the valve adapter, with a 1/4 inch wrench. Beware of leaking solvents.

2 Using a 17-mm wrench loosen the outlet valve adapter and remove the valve adapter from pump head.

3 Lift the valve adapter out of the housing in the pumphead.

4 With a pair of tweezers carefully remove valve assembly.

Replacing an Inlet/Outlet Valve

1 Before inserting the new valve assembly, clean the valve adapter by placing it into an ultrasonic bath, if it shows visible signs of contamination. Clean the valve housing in the pumphead by filling a syringe with alcohol and flushing the housing thoroughly.

2 Insert a new valve assembly into the valve adapter. The arrow on Figure 25 on page 117 indicates the flow direction. Make sure the valve assembly is fully inserted into the valve adapter.

NOTE
The side of the valve assembly that has the two holes must always face in flow direction!

3 Insert the valve adapter with the new valve assembly into the housing and screw tight.

4 Reconnect all capillaries and tubings.
NOTE

Don’t reverse inlet and outlet valve adapters. The outlet valve adapters have a smaller hole for fitting of the SST outlet capillary. The inlet adapters are designed for the finger tight fittings of the inlet tubing.
Exchanging the Filter Cup

When
- After the pump seals have been exchanged
- When the back pressure exceeds 10 bar pumping 50 ml/min of pure water with open purge valve.

Tools required
- Wrench 17 mm
- Wash bottle containing isopropanol

Parts required

<table>
<thead>
<tr>
<th>#</th>
<th>Part number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3150-0942</td>
<td>Filter cup</td>
</tr>
</tbody>
</table>

**NOTE** Whenever replacing the filters on the multi assembly is required because of a pump seal change or because excessive back pressure indicates the need for a replacement, make sure to replace the filter cup first and then the filter frit (see “Exchanging the Filter Frit” on page 122), after having pumped another 200 ml of solvent.

**NOTE** It is not possible to clean a contaminated filter cup in an ultrasonic bath because any contamination of the filter is normally permanent.

1. Using a 17 mm wrench loosen filter screw on the multi assembly.
2. Carefully pull out filter screw and filter cup.
3 Remove the filter cup from the screw by holding the screw and filter and pulling them apart.

**NOTE**

Generally, all components which are in direct contact with solvents should be handled wearing gloves.

![Diagram of filter components](image)

**Figure 26**   Exchanging the Filter Cup

4 Before reinserting the new filter screw into the multi assembly, wash the filter housing thoroughly with a wash bottle, containing Isopropanol, to remove any contamination.

5 Install a new filter into the filter screw.

6 Reinsert the filter and filter screw and turn until finger tight, then another 1/8 turn using a 17 mm wrench.

**NOTE**

Do not overtighten the filter screw. Excessive force on the filter screw doesn’t help in case of a leak.

7 Pump about 200 ml of solvent before replacing the filter frit installed at the multi assembly: the filter frit between the outlet of the multi assembly and the EMPV (see “Exchanging the Filter Frit” on page 122).
### Exchanging the Filter Frit

**NOTE** Whenever replacing the filters on the multi assembly is required because of a pump seal change or because excessive back pressure indicates the need for a replacement, make sure to replace the filter cup first (see “Exchanging the Filter Cup” on page 120) and then the filter frit, after having pumped another 200 ml of solvent.

### Changing the Filter Frit

**When**

When the back pressure exceeds 10 bar pumping 50 ml/min of pure water with open purge valve. After 200 ml solvent have been pumped through the pump after a filter cup exchange.

**Tools required**

- Wrench 7/16 inch
- Wrench 1/4 inch
- Hex-key 4 mm
- Wash bottle containing Isopropanol

**Parts required**

<table>
<thead>
<tr>
<th>#</th>
<th>Part number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>5022-2192</td>
<td>Filter frit 2 µm</td>
</tr>
</tbody>
</table>

1. Using a 1/4 inch wrench disconnect the capillary between multi assembly and EMPV.
2 Insert a hex-key into hole in the multi assembly. Hold the hex-key firmly and unscrew the locknut using the 7/16 inch wrench.

3 Pull out the filter holder and filter.

4 Flush the filter port and filter holder using a wash bottle containing isopropanol.
7 Maintenance
Simple Repairs

5 Install a new filter frit into the filter holder with the collar of the filter frit facing towards the multi assembly. Reconnect the filter holder into multi-assembly. Finger tighten screw and then turn 1/8 turn using 7/16 inch wrench and hex-key.

Figure 28 Changing the Filter Frit

6 Reconnect capillary between multi assembly and EMPV using a 1/4 inch wrench.
Exchanging the Seal Wash Pump Cartridge

When If mechanically defect

Parts required

<table>
<thead>
<tr>
<th>#</th>
<th>Part number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>5042-8507</td>
<td>Seal wash pump cartridge</td>
</tr>
</tbody>
</table>

1. Disconnect seal wash tubing at the connectors, and place the ends of each tubing at a level above seal wash bottle (to avoid leaking solvents).
2. By pressing the upper and lower clip remove the seal wash pump cartridge.
3. Replace the defective cassette and slide the new cassette on to the shaft pressing upper and lower clip. Push forward until the clips snap into place. The preferred orientation of the cartridge is as shown in picture below.
4. Reconnect seal wash tubing.

![Seal wash connectors]

**Figure 29** Seal Wash Pump Cartridge
Removing and Disassembling the Pump Head Assembly

When

- When leaky or blocked
- For exchanging the seals
- For exchanging the plungers

Tools required

- Screwdriver Pozidrive#1
- 4-mm hexagonal key
- 10-mm wrench
- Toothpick

Preparations

- Switch OFF preparative pump at power switch
- Remove the front cover to have access to the pump mechanics

**NOTE**

Seals should always be replaced as pairs (2x front seals + 2x back seals)!

**CAUTION**

Damage of the pump drive

Starting the pump when the pump head is removed may damage the pump drive.

➔ Never start the pump when the pump head is removed.
1. Disconnect the capillaries at the outlet valves and the tubes at the inlet valves. Beware of leaking solvents. Remove seal wash tubes.

2. Using a 4-mm hexagonal key step wise loosen and remove the four pump head screws and remove the pump head from the pump drive.

3. Place the pump head on a flat surface facedown. Pull out the plungers from the spring assembly.

4. Loosen the two screws on the spring assembly and carefully pull the spring assembly and pumphead apart.
7 Maintenance
Simple Repairs

5 Remove secondary seals between the pumphead and the spring assembly, by using the plungers.

Secondary seals
Reassembling the Pump Head Assembly

Tools required

- Screwdriver Pozidrive#1
- 4-mm hexagonal key
- 10-mm wrench

Preparations

Clean all parts before reassembly

1. Place front pump head facedown on a flat surface. Insert new seals with the spring facing the pump body. Press the seals firmly into place. Make sure not to damage seal surface.

2. Take rear pump head and place on top of front pump head. Beware that the O-rings are in proper place and the seal wash fitting is facing in same direction as outlet valves.
3 Insert and tighten special screws using a 10 mm wrench.

4 Insert new secondary seals with the spring facing the pump body. Press the seals firmly into place.

5 Place Spring assembly on special screws and tighten the two flathead screws using a pozidrive#1. The RF-tag must be on the upper side of the pumphead.

6 Reinsert Plungers by pushing until Plunger collars hit springs.
Exchanging the Optional Interface Board

When
Board defective

Parts required
#   Description
1   BCD (Interface) board, see “BCD / External Contact Board” on page 155

**CAUTION**

Electrostatic discharge at electronic boards and components

Electronic boards and components are sensitive to electrostatic discharge (ESD).

In order to prevent damage always use an ESD protection (for example, the ESD wrist strap from the accessory kit) when handling electronic boards and components.

1. Switch off the pump at the main power switch, unplug the pump from line power.
2. Disconnect cables from the interfaceboard connectors.
3. Loosen the screws. Slide out the interface board from the pump.
4. Install the new interface board. Secure screws.
5. Reconnect the cables to the board connector.

![Figure 30](image) Exchanging the Interface Board
Replacing the Module’s Firmware

When

The installation of newer firmware might be necessary
• if a newer version solves problems of older versions or
• to keep all systems on the same (validated) revision.

The installation of older firmware might be necessary
• to keep all systems on the same (validated) revision or
• if a new module with newer firmware is added to a system or
• if third part control software requires a special version.

Tools required

• LAN/RS-232 Firmware Update Tool or
• Agilent Diagnostic Software
• Instant Pilot G4208A (only if supported by module)
• Control Module G1323B (only if supported by module)

Parts required

Description
Firmware, tools and documentation from Agilent web site

Preparations

Read update documentation provided with the Firmware Update Tool.

To upgrade/downgrade the module’s firmware the following steps have to be performed:

1 Download the required module firmware, the latest LAN/RS-232 FW
   Update Tool and the documentation from the Agilent web.

2 Load the firmware into the module as described in the documentation.

NOTE

Due to a different hardware platform, there is no way to convert a G1314D VWD and the
G1314E VWD SL Plus to a G1314A/B VWD or G1314C VWD SL.

Main Power Supply Assembly 164
Preparative Pump Main Board (PPM)

The board controls all information and activities of all assemblies within the preparative pump. The operator enters parameters, changes modes and controls the preparative pump through interfaces (CAN or RS-232C), connected to the user-interfaces. Figure 35 on page 152 and Figure 36 on page 153 show block diagrams of this board.

ASIC — Application-Specific Integrated Circuit

The application-specific integrated circuit (ASIC) includes all digital logic for the core processor functions and also for module-specific functions.

Motor Drive

The drive comprises motor control and motor amplifier.

Electromechanical Proportional Valve

The EMPV consists of an electro-magnetic solenoid, driven by a PWM (Pulse Width Modulator).

Pressure Converter

This block comprises a filter and amplifier for the pressure-sensor-signal, an A/D converter with integrated multiplexer.

Leak Converter

This block comprises a PTC for the leak identification and a NTC for the ambient temperature measurement. This assures that temperature changes are not identified as leak. A leak would cool down the PTC and its change in resistance results in a leak signal.
Fan Drive

The revolution of the fan is controlled by the main processor depending on the internal heat distribution in the preparative pump. The fan provides a PWM signal which is proportional to the revolution. This fan status signal is used for diagnostics.

Seal Wash Pump Drive

The drive comprises a current control and full bridge driver for the seal wash pump.

Pump head ID Module

The pump head ID Module is used to write pump head specific information onto a tag that is installed in the pump head.

Index Board

The Index board is used to sense the movement and positioning of the pump drive. It also comprises calibration information of the drive.

Electronic Fuses

The valve circuit is electronically fused on the board. Any error on the board or shortages of the valve will activate the electronic fuse that will switch OFF the supply voltage. This prevents the damage of components.

Onboard Battery

An onboard lithium battery buffers the electronic memories when the preparative pump is turned off.

For safety information on lithium batteries, see “Lithium Batteries Information” on page 173.

Figure 37 Interconnection Diagram CSM Board
Optional Interface Boards

**BCD / External Contact Board**

The Agilent 1100/1200 Series modules have one optional board slot that allows to add an interface board to the modules. Some modules do not have this interface slot. Refer to “Agilent 1100/1200 Series Interfaces” on page 16 for details.

</tr>
</tbody>
</table>

The BCD board provides a BCD output for the bottle number of the Agilent 1200 Series autosampler and four external contacts. The external contact closure contacts are relay contacts. The maximum settings are: 30 V (AC/DC); 250 mA (fused).
There are general purpose cables available to connect the BCD output, see BCD Cables in the Service Manual and the external outputs, see External Contact Cable in the Service Manual to external devices.

LAN Communication Interface Board

The Agilent 1100/1200 Series modules have one optional board slot that allows to add an interface board to the modules. Some modules do not have this interface slot. Refer to “Agilent 1100/1200 Series Interfaces” on page 16 for details.

Agilent 1200 Series Interfaces

Analog Signal Output

The analog output connector(s) provide an analog signal output (pressure signal). The analogue data are digitalized by an A/D-converter and can then be distributed to a PC, which is running with a non-Agilent operating system that does not communicate via GPIB.

For details refer to the description of the main board of the module.

GPIB Interface

The GPIB connector serves as the default interface between an Agilent 1200 Series module and the Agilent Control Software.

The GPIB connector is used to connect the module with a computer. The address and control switches next to the GPIB connector determine the GPIB address of your module. The switches are preset to a default address and recognized by the operating software from Agilent Technologies.

CAN Interface

The CAN connectors serve as the interface between the Agilent 1200 Series modules themselves. All modules in the Stack must be interconnected. It is a 2 wire serial bus system supporting high speed data communication and real-time requirements.
APG Remote Interface

The APG Remote connector serves as the interface between the Agilent 1200 Series and other Agilent (APG remote compatible) products. It may be used in combination with other analytical instruments from Agilent Technologies if you want to use features as common shut down, prepare, and so on.

Remote control allows easy connection between single instruments or systems to ensure coordinated analysis with simple coupling requirements.

The subminiature D connector is used. The module provides one remote connector which is inputs/outputs (wired-or technique).

To provide maximum safety within a distributed analysis system, one line is dedicated to SHUT DOWN the system's critical parts in case any module detects a serious problem. To detect whether all participating modules are switched on or properly powered, one line is defined to summarize the POWER ON state of all connected modules. Control of analysis is maintained by signal readiness READY for next analysis, followed by START of run and optional STOP of run triggered on the respective lines. In addition PREPARE and START REQUEST may be issued. The signal level are defined as:

- standard TTL levels (0 V is logic true, + 5 V is false)
- fan-out is 10,
- input load is 2.2 kOhm against + 5 V, and
- output are open collector type, inputs/outputs (wired-or technique).
### Table 25  Remote Signal Distribution

<tr>
<td>9</td>
<td>START REQUEST</td>
<td>(L) Request to start injection cycle (for example, by start key on any module). Receiver is the autosampler.</td>
</tr>
</tbody>
</table>
RS-232C

The RS-232C connector is used to control the instrument from a computer through RS-232C connection, using the appropriate software. The RS-232C interface can be used for controlling the module with PCs running non-Agilent Control Software. Most (but not all) of the Control Software products of other manufacturers communicate via this RS-232C interface. If in such a scenario the RS-232C interface cannot be used, the analog output connector can be used instead, in which case an additional handheld controller (connected via the CAN Connector) must be used.

The RS-232C connector can be configured with the configuration switch module next to the GPIB connector. The RS-232C is designed as DCE (data communication equipment) with a 9-pin male SUB-D type connector. The pins are defined as:

**Figure 38**  RS-232 Cable
Main Power Supply Assembly

The main power supply comprises a closed assembly (no on-site repair possibility).

The power supply provides all DC voltages used in the module except for the voltages supplied by the lamp power supply to the deuterium and tungsten lamps in the detectors. The line voltage can vary in a range from 100 – 240 volts AC ± 10% and needs no manual setting.

![Main Power Supply (MPS) Blockdiagram](image)

Figure 39  Main Power Supply (MPS) Blockdiagram

No accessible hardware fuse is needed because the main power supply is safe against any short circuits or overload conditions on the output lines. When overload conditions occur, the power supply turns off all output voltages. Turning the line power off and on again resets the power supply to normal operation if the cause of the overload condition has been removed.
An over-temperature sensor in the main power supply is used to turn OFF output voltages if the temperature exceeds the acceptable limit (for example, if the cooling fan of the instrument fails). To reset the main power supply to normal operating conditions, turn the instrument OFF, wait until it is approximately at ambient temperature and turn the instrument on again.

The following table gives the specifications of the main power supply.

General Safety Information

The following general safety precautions must be observed during all phases of operation, service, and repair of this instrument. Failure to comply with these precautions or with specific warnings elsewhere in this manual violates safety standards of design, manufacture, and intended use of the instrument. Agilent Technologies assumes no liability for the customer’s failure to comply with these requirements.

**WARNING**

Ensure the proper usage of the equipment.
The protection provided by the equipment may be impaired.

➔ The operator of this instrument is advised to use the equipment in a manner as specified in this manual.

Safety Standards

This is a Safety Class I instrument (provided with terminal for protective earthing) and has been manufactured and tested according to international safety standards.
Operation

Before applying power, comply with the installation section. Additionally the following must be observed.

Do not remove instrument covers when operating. Before the instrument is switched on, all protective earth terminals, extension cords, auto-transformers, and devices connected to it must be connected to a protective earth via a ground socket. Any interruption of the protective earth grounding will cause a potential shock hazard that could result in serious personal injury. Whenever it is likely that the protection has been impaired, the instrument must be made inoperative and be secured against any intended operation.

Make sure that only fuses with the required rated current and of the specified type (normal blow, time delay, and so on) are used for replacement. The use of repaired fuses and the short-circuiting of fuse holders must be avoided.

Some adjustments described in the manual, are made with power supplied to the instrument, and protective covers removed. Energy available at many points may, if contacted, result in personal injury.

Any adjustment, maintenance, and repair of the opened instrument under voltage should be avoided whenever possible. When inevitable, this has to be carried out by a skilled person who is aware of the hazard involved. Do not attempt internal service or adjustment unless another person, capable of rendering first aid and resuscitation, is present. Do not replace components with power cable connected.

Do not operate the instrument in the presence of flammable gases or fumes. Operation of any electrical instrument in such an environment constitutes a definite safety hazard.

Do not install substitute parts or make any unauthorized modification to the instrument.

Capacitors inside the instrument may still be charged, even though the instrument has been disconnected from its source of supply. Dangerous voltages, capable of causing serious personal injury, are present in this instrument. Use extreme caution when handling, testing and adjusting.
When working with solvents please observe appropriate safety procedures (e.g. goggles, safety gloves and protective clothing) as described in the material handling and safety data sheet by the solvent vendor, especially when toxic or hazardous solvents are used.
Safety Symbols

</tr>
</tbody>
</table>

**WARNING**
alerts you to situations that could cause physical injury or death.

➔ Do not proceed beyond a warning until you have fully understood and met the indicated conditions.

**CAUTION**
alerts you to situations that could cause loss of data, or damage of equipment.

➔ Do not proceed beyond a caution until you have fully understood and met the indicated conditions.
Appendix

The Waste Electrical and Electronic Equipment (WEEE) Directive
(2002/96/EC)

Abstract

NOTE

This product complies with the WEEE Directive (2002/96/EC) marking requirements. The affixed label indicates that you must not discard this electrical/electronic product in domestic household waste.

Product Category:

With reference to the equipment types in the WEEE Directive Annex I, this product is classed as a “Monitoring and Control Instrumentation” product.

NOTE

Do not dispose off in domestic household waste

To return unwanted products, contact your local Agilent office, or see www.agilent.com for more information.
Lithium Batteries Information

WARNING Lithium batteries may not be disposed-off into the domestic waste. Transportation of discharged Lithium batteries through carriers regulated by IATA/ICAO, ADR, RID, IMDG is not allowed.

Danger of explosion if battery is incorrectly replaced.

➔ Discharged Lithium batteries shall be disposed off locally according to national waste disposal regulations for batteries.

➔ Replace only with the same or equivalent type recommended by the equipment manufacturer.

WARNING Lithiumbatteri - Eksplosionsfare ved fejlagtig håndtering.

Udskiftning må kun ske med batteri af samme fabrikat og type.

➔ Lever det brugte batteri tilbage til leverandøren.

WARNING Lithiumbatteri - Eksplosionsfare.

Ved udskiftning benyttes kun batteri som anbefalt av apparatfabrikanten.

➔ Brukt batteri returneres appararleverandoren.

NOTE Bij dit apparaat zijn batterijen geleverd. Wanneer deze leeg zijn, moet u ze niet weggooien maar inleveren als KCA.
Radio Interference

Cables supplied by Agilent Technologies are screened to provide optimized protection against radio interference. All cables are in compliance with safety or EMC regulations.

Test and Measurement

If test and measurement equipment is operated with unscreened cables, or used for measurements on open set-ups, the user has to assure that under operating conditions the radio interference limits are still met within the premises.
Sound Emission

Manufacturer’s Declaration

This statement is provided to comply with the requirements of the German Sound Emission Directive of 18 January 1991.

This product has a sound pressure emission (at the operator position) < 70 dB.

• Sound Pressure $L_p < 70$ dB (A)
• At Operator Position
• Normal Operation
• According to ISO 7779:1988/EN 27779/1991 (Type Test)
Solvent Information

Flow Cell

To protect optimal functionality of your flow-cell:

- Avoid the use of alkaline solutions (pH > 9.5) which can attack quartz and thus impair the optical properties of the flow cell.
- If the flow cell is transported while temperatures are below 5 degree C, it must be assured that the cell is filled with alcohol.
- Aqueous solvents in the flow cell can built up algae. Therefore do not leave aqueous solvents sitting in the flow cell. Add a small % of organic solvents (e.g. acetonitrile or methanol ~5%).

Use of Solvents

Observe the following recommendations on the use of solvents.

- Brown glass ware can avoid growth of algae.
- Small particles can permanently block capillaries and valves. Therefore always filter solvents through 0.4 µm filters.
- Avoid the use of the following steel-corrosive solvents:
  - Solutions of alkali halides and their respective acids (for example, lithium iodide, potassium chloride, and so on),
  - High concentrations of inorganic acids like sulfuric acid and nitric acid, especially at higher temperatures (if your chromatography method allows, replace by phosphoric acid or phosphate buffer which are less corrosive against stainless steel),
  - Halogenated solvents or mixtures which form radicals and/or acids, for example:
    \[
    2\text{CHCl}_3 + \text{O}_2 \rightarrow 2\text{COCl}_2 + 2\text{HCl}
    \]
    This reaction, in which stainless steel probably acts as a catalyst, occurs quickly with dried chloroform if the drying process removes the stabilizing alcohol,
Appendix 10
Solvent Information

- Chromatographic grade ethers, which can contain peroxides (for example, THF, dioxane, di-isopropylether) such ethers should be filtered through dry aluminium oxide which adsorbs the peroxides,
- Solvents containing strong complexing agents (e.g. EDTA),
- Mixtures of carbon tetrachloride with 2-propanol or THF.

wrench 1/4 inch 96, 99
wrong data from pressure sensor 84
In This Book

This manual contains technical reference information about the Agilent 1200 Series preparative pump. The manual describes the following:

- introduction,
- requirements,
- installation,
- using the pump,
- optimizing performance,
- troubleshooting and diagnostics,
- maintenance
- parts and materials,
- identifying cables,
- configuring the pump,
- legal, safety and warranty information.
